Experiment No. 2
Analyze the Titanic Survival Dataset and apply appropriate regression technique.
Date of Performance:
Date of Submission:

Aim: Analyze the Titanic Survival Dataset and apply appropriate Regression Technique.

Vidyavardhini's College of Engineering & Technology Department of Computer Engineering

Objective: Able to perform various feature engineering tasks, apply logistic regression on the given dataset and maximize the accuracy.

Theory:

Logistic Regression was used in the biological sciences in early twentieth century. It was then used in many social science applications. Logistic Regression is used when the dependent variable(target) is categorical and is binary in nature. In order to perform binary classification the logistic regression techniques makes use of Sigmoid function.

For example,

To predict whether an email is spam (1) or (0)

Whether the tumor is malignant (1) or not (0)

Consider a scenario where we need to classify whether an email is spam or not. If we use linear regression for this problem, there is a need for setting up a threshold based on which classification can be done. Say if the actual class is malignant, predicted continuous value 0.4 and the threshold value is 0.5, the data point will be classified as not malignant which can lead to serious consequence in real time.

From this example, it can be inferred that linear regression is not suitable for classification problem. Linear regression is unbounded, and this brings logistic regression into picture. Their value strictly ranges from 0 to 1.

Dataset:

The sinking of the Titanic is one of the most infamous shipwrecks in history.

On April 15, 1912, during her maiden voyage, the widely considered “unsinkable” RMS Titanic sank after colliding with an iceberg. Unfortunately, there weren’t enough lifeboats for everyone onboard, resulting in the death of 1502 out of 2224 passengers and crew.

While there was some element of luck involved in surviving, it seems some groups of people were more likely to survive than others.

In this challenge, we ask you to build a predictive model that answers the question: “what sorts of people were more likely to survive?” using passenger data (ie name, age, gender, socio-economic class, etc).

From this example, it can be inferred that linear regression is not suitable for classification problem. Linear regression is unbounded, and this brings logistic regression into picture. Their value strictly ranges from 0 to 1.

Variable	Definition	Key
survival	Survival	0 = No, 1 = Yes
pclass	Ticket class	1 = 1st, 2 = 2nd, 3 = 3rd
sex	Sex	
Age	Age in years	
sibsp	# of siblings / spouses aboard the Titanic	
parch	# of parents / children aboard the Titanic	
ticket	Ticket number	
fare	Passenger fare	
cabin	Cabin number	
embarked	Port of Embarkation	C = Cherbourg, Q = Queenstown, S = Southampton

Variable Notes pclass: A proxy for socio-

economic status (SES) 1st = Upper, 2nd =

Middle, 3rd = Lower

Vidyavardhini's College of Engineering & Technology Department of Computer Engineering

age: Age is fractional if less than 1. If the age is estimated, is it in the form of xx.5

sibsp: The dataset defines family relations in this way...,

Sibling = brother, sister, stepbrother, stepsister

Spouse = husband, wife (mistresses and fiancés were ignored)

parch: The dataset defines family relations in this way...

Parent = mother, father

Child = daughter, son, stepdaughter, stepson

Some children travelled only with a nanny, therefore parch=0 for them.

Code:

```
import numpy as np import pandas as pd

from sklearn import preprocessing import

matplotlib.pyplot as plt plt.rc("font",

size=14) import seaborn as sns

sns.set(style="white")

sns.set(style="whitegrid", color_codes=True)

train_df = pd.read_csv("../input/train.csv")

test_df = pd.read_csv("../input/test.csv")

# Train data train_df.head()
```

```
Train/Test split results:  
LogisticRegression accuracy is 0.782  
LogisticRegression log_loss is 0.504  
LogisticRegression auc is 0.839
```

```
Using a threshold of 0.071 guarantees a sensitivity of 0.962 and a specificity of 0.200, i.e. a false positive rate of 80.00%.
```

Conclusion:

1. Features have been chosen to develop the model:

1. P_class: A proxy for socio-economic status (SES)
1st = Upper, 2nd = Middle, 3rd = Lower.
2. Age: Age is fractional if it is less than 1.
If the age is estimated, is it in the form of xx.5
3. Survival: Yes = 1, No = 0
4. Sex: Male(M) / Female(F)

Vidyavardhini's College of Engineering & Technology Department of Computer Engineering

5. Parch: Number of Parents / Children

6. Embarked: Port of Embarkation

C = Cherbourg, Q = Queenstown, S = Southampton

2. Accuracy obtained:

- Using the Scikit-Learn Logistic_Regression class, we train a logistic regression model on the training data.
- The model's predict method is then used to forecast the classes of the testing set. Finally, we use scikit-learn's accuracy_score function to determine the model's accuracy.
- Accuracy of logistic regression is 0.782.
